2. Automation (programming) – Automation, also called computer automation, in computing, is the use of a computer to perform tasks that were previously done manually. For example, manufacturing automation uses software to control robotic machinery and then programming to control the software, some other examples of automation include automatic translation and speech recognition software, medical image processing, web site traffic analysis, and managing large amounts of data. In addition, the term general automation may be used to refer to the idea of building a machine or system that would perform a sequence of tasks automatically. As a subfield of artificial intelligence, automata are a particular kind of formal system in which state transitions are determined by an algorithm. The most basic kind of automaton is a finite state machine and they can be used to model flow diagrams, such as flowcharts or decision trees. During the 1970s, when the first microcomputers became widely available, for many years, computer-based automation systems were perceived as the antithesis of the machine, and it was generally assumed that these systems would never be competitive with the human workforce. This is attributed to the way automation is performed, and the amount of manual effort needed. This view changed in the early 21st century with the advent of digital manufacturing, which has completely reconfigured the factory floor, as factories are now built with workers directly connected to digital equipment, and there is no intermediate machine needed to perform work. For example, a 3D printer can provide a job to a worker in minutes instead of hours. However, there are still some processes in industrial automation that are inherently impossible or very difficult to automate. The robotic arm is a good example of this, since it is impossible to control any physical movement exactly, when the job is complete, the arm must still be manually removed from the printed object, and thus removed from the working area. In contrast, if an object was printed directly into the output bin, the automated assembly line is a good example of automation that requires significant effort in the design phase. A fully automated assembly line would require very little, if any, human intervention, once the parts are delivered, they would all be automatically stacked, and the line would be stopped until the next part was delivered. This is one of the most common examples of automation in manufacturing. Autodesk Revit provides a concept called worklist that provides visibility into the jobs in the project at any given time. It is used to manage parts in the project 3. Automation (2d92ce491b
